Research Collaboration and Evidence-Based ML Research with LUNA · Quiz explanations

Original formative checkpoint explanations; no graded assignment.

1. Why does closing a research issue not establish a scientific claim?

It records workflow completion against task criteria. Scientific support still requires appropriate data, comparisons, analysis and review of limitations.

2. What should you check when a document is missing from a project view?

Check the original and authorized access, project metadata, connector scope and collection status. Missing visibility does not prove that work never occurred.

3. Why compare methods using matched run identifiers?

Matching controls the evaluation conditions. Independent sorting breaks that correspondence and can hide the distribution of within-run differences.

4. What does a metadata audit fail to prove?

Nonempty fields do not verify their truth, source accessibility, absence of leakage, scientific validity, novelty or generalization.

5. When is an AI assistant right to withhold a research-readiness judgment?

When the supplied or accessible records do not support it. It should identify the missing evidence rather than infer readiness from references or fluent summaries.

6. How will this workflow support the Week 4 variational-inference experiment?

Record the model, inference method, exact reference, settings and diagnostics; separate convergence from approximation quality and qualify the supported claim.
